4-((Trimethylsilyl)ethynyl)benzothiadiazole (S1).
The synthesis of S1 is a modified version of a reported procedure. To a solution of 4-bromobenzothiadiazole (500 mg, 2.33 mmol) dissolved in tetrahydrofuran (20.8 mL) was added Pd(PPh$_3$)$_4$ (161.8 mg, 0.14 mmol), CuI (26.7 mg, 0.14 mmol), and triethylamine (16.6 mL). After stirring for 5 minutes, trimethylsilylacetylene (0.38 mL) was added and stirred for another 18 hours at 60 °C under nitrogen. The resulting dark brown mixture was extracted with dichloromethane and water. After several extractions, the combined organic layer was washed with brine, dried over anhydrous Na$_2$SO$_4$, filtered, and concentrated under reduced pressure via rotary evaporation. Purification by column chromatography (SiO$_2$, petroleum ether/dichloromethane = 1:1) afforded dark yellow liquid (385 mg, 71%). $^1$H NMR (400 MHz, CDCl$_3$): δ 7.76 (d, $J$ = 8.0 Hz, 1H), 7.55 (d, $J$ = 8.0 Hz, 1H), 7.32 (dd, $J$ = 8.0 Hz, 1H), 0.15 (s, 9H); LC-MS (ESI) obsd 233.0 calcd 233.1 [(M+H)$^+$, M = C$_{11}$H$_{12}$N$_2$SSi].

Extinction Coefficients Measurement Methods

Stock solutions of samples were prepared with volumetric flasks through the dissolution of weighted samples in HPLC grade methanol. An aliquot of the stock solutions was then diluted according to the factors in Table S1 with methanol to around 3 mL. Absorption spectra of the resulting diluted solutions were measured at room temperature with a two-sided glass cuvette (1 cm × 1 cm) without deaeration, affording absorbance in the range of 0.6 to 1.3. The extinction coefficient of each compound at the peak wavelength was then calculated based on the Beer’s Law.

Dye-Sensitized Solar Cells Fabrication Methods

The assembly of the dye-sensitized solar cells was based on a previously reported method. Electrodes used for the TiO$_2$ thin film working electrodes and counter electrodes were transparent conductive fluorine:SnO$_2$ glass (FTO, 7 $\Omega$/square, Hartford Glass). The FTO was pre-treated prior to the deposition of TiO$_2$ films by immersing in a solution of 40 mM titanium (IV)-chloride-THF complex at 75 °C for a period of 30 minutes. The treated films were sintered in a box furnace at 370 °C and 570 °C for periods of 5 minutes and 30 minutes, respectively.

Deposition of the TiO$_2$ films was done by doctor-blading the TiO$_2$ paste obtained from Solaronix (14411,T-SP, 15 – 20 nm TiO$_2$ nanoparticles) to produce a reproducible thickness of 15 $\mu$m for a transparent TiO$_2$ layer, and the resulting films were annealed at 370 °C for a period of 10 minutes and at 470 °C for a period of 30 minutes. These films were subsequently treated with TiCl$_4$ by immersing in a solution of TiCl$_4$ at 75 °C for a period of 30 minutes, and then they were sintered in a box furnace at 370 °C and 570 °C for periods of 5 minutes and 30 minutes, respectively. The films were taken out of the box at 100 °C and sensitized in a staining jar of fresh 0.2 mM dyad/porphyrin in methanol (17 mL) for a period of 17.5 hours in the dark at room temperature. Each porphyrin/dyad film was prepared in quadruplets.

The counter electrodes were prepared on FTO glass (15 $\Omega$/square, Hartford Glass) via a deposition of chloroplatinic acid (H$_2$PtCl$_6$) solution in ethanol, followed by a heat treatment to crystallize the platinum at 450 °C for 30 minutes. The complete dye-sensitized solar cells were prepared by sealing the working and counter electrodes together with a 60 $\mu$m thick hot-melt film spacer (Surlyn), which serves as both a sealant and spacer. The electrolyte was prepared from a combination of 1,2-dimethyl-3-propylimidazolium iodide (DMPII, TCI, 0.6 M), lithium iodide (anhydrous, 99.95%, Alfa Aesar, 0.1 M), iodine (pure, Acros Organics, 0.2 M), 4-tert-butylpyridine (TBP, Sigma-Aldrich, 0.5 M) and anhydrous acetonitrile as the solvent (Omni Solv, EMD Millipore). The electrolyte solution was inserted into the cell through a pre-drilled hole in the counter electrode via vacuum back-filling method. Prior to this step, the hole in the counter electrode was sealed with a glass cover-slip and hot-melt film. The active area of each cell was 0.25 cm$^2$. The J-V curves were performed without a mask.
